Stake settings

- High importance - medical texts from a dataset Eric has ContracTICO
- Low importance - hotel like price description

Task description

- Give user a document in foreign language
- Ask them if they would accept a given translation
- Give the participants all explanations and ask for them to rank each.

Explanation types

- No explanation
- “Rational generation” -> just use LLM to make some kind of explanation
- Could add something like back translations where we literally just translate the output of the model back into the users own language and show them that (discussed in https://aclanthology.org/2025.emnlp-main.606.pdf)
- Some type of numeric explanation
    - Potentially Quality Estimation (smth from https://arxiv.org/pdf/2503.03044)
    - Estimate word association from attention

Independent variables

- Translation quality - in the ContracTICO there are plausible flawed translations (they only go from english document to flawed spanish translation)
- Stakes - high vs low that is
- Explanation types - see above (3-4).

Survey design

Pre/Post Interview Questions
Qualitative Data we can get from them

Learn about people’s preexisting notions of machine translation – do they interact with it? How? Are there ever any issues?
From Ki et al.

Pre-/Post-Task Survey. Before starting the main study, each participant is asked to answer four pre-task questions regarding their first language, pro-

ficiency in English and Spanish, and frequency of using AI translation tools in daily life or work. After completing the main study, each participant answers three post-task questions about their experience with the randomly assigned condition in terms of perceived mental burden, helpfulness, and trust for future use (Hoffman et al., 2019). Detailed descriptions are provided in Appendix C.1.

Stealing from his paper:
Five Main Survey Questions (Ehsan et al., 2024)

Participants watched three robots perform the same task, each providing a different kind of explanation. They ranked all three robots on five dimensions and justified their rankings with open-ended responses.

1. Understandability: How understandable each robot's explanation was.
2. Confidence: Their confidence in each robot's ability to complete its task.
3. Intelligence: Each robot's perceived intelligence.

These were comparative rankings (1st–3rd), not Likert-scale ratings. Participants also provided mandatory written justifications for each ranking.
